

# Computer Vision II: Multiple View Geometry (IN2228)

## Chapter 12 Bundle Adjustment (Part 1 Fundamentals)

Dr. Haoang Li

06 July 2023 11:00-11:45

# Announcement Before Class

## ➤ Updated Lecture Schedule

For updates, slides, and additional materials:

<https://cvg.cit.tum.de/teaching/ss2023/cv2>

90-minute course; 45-minute course

Wed 19.04.2023 Chapter 00: Introduction  
Thu 20.04.2023 Chapter 01: Mathematical Backgrounds

Wed 26.04.2023 Chapter 02: Motion and Scene Representation (Part 1)  
Thu 27.04.2023 Chapter 02: Motion and Scene Representation (Part 2)

Wed 03.05.2023 Chapter 03: Image Formation (Part 1)  
Thu 04.05.2023 Chapter 03: Image Formation (Part 2)

Foundation

Wed 10.05.2023 Chapter 04: Camera Calibration  
Thu 11.05.2023 Chapter 05: Correspondence Estimation (Part 1)

Wed 17.05.2023 Chapter 05: Correspondence Estimation (Part 2)  
Thu 18.05.2023 No lecture (Public Holiday)

Wed 24.05.2023 No lecture (Conference)  
Thu 25.05.2023 No lecture (Conference)

} Videos and reading materials  
about the combination of deep  
learning and multi-view geometry

Wed 31.05.2023 Chapter 05: Correspondence Estimation (Part 3)

Thu 01.06.2023 Chapter 06: 2D-2D Geometry (Part 1)

Wed 07.06.2023 Chapter 06: 2D-2D Geometry (Part 2)

Thu 08.06.2023 No lecture (Public Holiday)

Wed 14.06.2023 Chapter 06: 2D-2D Geometry (Part 3)

Thu 15.06.2023 Chapter 06: 2D-2D Geometry (Part 4)

Core part

Wed 21.06.2023 Chapter 07: 3D-2D Geometry

Thu 22.06.2023 Chapter 08: 3D-3D Geometry

Wed 28.06.2023 Chapter 09: Single-view Geometry

Thu 29.06.2023 Chapter 10: Combination of Different Configurations

Wed 05.07.2023 Chapter 11: Photometric Error and Direct Method

Thu 06.07.2023 Chapter 12: Bundle Adjustment (Part 1)

Wed 12.07.2023 Chapter 12: Bundle Adjustment (Part 2)

Chapter 13: Robust Estimation

Advanced topics and  
high-level tasks

Thu 13.07.2023 Exam Information and Knowledge Review

Wed 19.07.2023 Chapter 14: SLAM and SFM

Thu 20.07.2023 No Onsite Lecture. Alternative: Online Meeting for Question Answering

## Today's Outline

- Error Metrics
- Definition of Bundle Adjustment
- Basic Knowledge of Non-linear Optimization
- Application of Non-linear Optimization to Bundle Adjustment Based on Lie Algebra (next class)

# Error Metrics

## ➤ Overview

- ✓ The quality of the estimated camera pose can be measured using different error metrics:
  - Algebraic error
  - Epipolar Line Distance (only for 2D-2D)
  - Reprojection Error
- ✓ By minimizing any of the above error, we can optimize the camera pose.
- ✓ The above metrics are not limited to 2D-2D. We can also use them to evaluate 3D-2D case. In our class, let us take 2D-2D for example.

# Error Metrics

## ➤ Algebraic Error

- ✓ We consider 8-point algorithm for illustration. It seeks to minimize the **algebraic error**:

$$err = \|QE\|^2 = \sum_{i=1}^N (\bar{p}_2^{iT} E \bar{p}_1^i)^2$$

- ✓ From the derivation of the epipolar constraint and the property of dot product, we can observe:

$$\|\bar{p}_2^T E \bar{p}_1\| = \underbrace{\|\bar{p}_2^T \cdot (E \bar{p}_1)\|}_{\text{Associative law}} = \underbrace{\|\bar{p}_2\| \|E \bar{p}_1\| \cos(\theta)}_{\text{Property of dot product}}$$

$$= \|\bar{p}_2\| \| [T_{\times}] R \bar{p}_1 \| \cos(\theta)$$

Definition of essential matrix (in right camera frame)

# Error Metrics

## ➤ Algebraic Error

- ✓ We can see that this product depends on the angle  $\theta$  between  $\bar{p}_2$  and the **normal** to the epipolar plane.
- ✓ It is nonzero when  $\bar{p}_1, \bar{p}_2$ , and  $T$  are not coplanar.

$$= \|\bar{p}_2\| \|[T_\times] R \bar{p}_1\| \cos(\theta)$$

Normal in the right  
camera frame

# Error Metrics

## ➤ Epipolar Line Distance (only for 2D-2D configuration)

✓ Sum of squared epipolar-line-to-point distances:

$$err = \sum_{i=1}^N \left( d(p_1^i, l_1^i) \right)^2 + \left( d(p_2^i, l_2^i) \right)^2$$

✓ Cheaper than reprojection error (introduced later) because does not require point triangulation

Left point

$$\begin{bmatrix} u_2^i \\ v_2^i \\ 1 \end{bmatrix}^T \begin{bmatrix} u_1^i \\ v_1^i \\ 1 \end{bmatrix} = 0$$

The matrix  $F$  is highlighted in a red box, representing the Fundamental Matrix.

Fundamental Matrix  $F = K_2^{-T} E K_1^{-1}$

Point lies on a line:  $\text{dot}(p, l) = 0$

Epipolar line computed by the right point

# Error Metrics

## ➤ Reprojection Error

- ✓ Sum of the Squared Reprojection Errors 
$$err = \sum_{i=1}^N \|p_1^i - \pi(P^i, K_1, I, 0)\|^2 + \|p_2^i - \pi(P^i, K_2, R, T)\|^2$$
- ✓ More expensive than the previous errors because it requires to first **triangulate** the 3D points.

# Error Metrics

## ➤ Reprojection Error

- ✓ It is the most popular because more accurate. The reason is that the error is computed directly with respect to the original input data, i.e., the image points. It is point-to-point distance.
- ✓ Previous algebraic error is with respect to 3D direction; Epipolar line distance is a point-to-line distance.
- ✓ Reprojection error is commonly called “golden standard” in our society. For a systematic analysis, please refer to [1].

[1] “Multiple View Geometry in Computer Vision”: R. Hartley and A. Zisserman

# Error Metrics

## ➤ Reprojection Error

- ✓ We often use reprojection error to perform two tasks:
  - Pose and 3D point optimization
  - Accuracy evaluation

Bundle adjustment for optimization

Calibration evaluation

# Error Metrics

## ➤ Error Minimization

- ✓ Let us consider 8-point method. For **more than 8 points**, error will only be 0 if there is **no noise** in the data (if there is image noise, the linear system becomes overdetermined)
- ✓ We aim to find the optimal camera pose to minimize the least-squares error.

# Bundle Adjustment

## ➤ Definition

- ✓ We extend two-view reprojection minimization to multi-view case, which is called “bundle adjustment”.
- ✓ We typically treat the first camera as the world frame.
- ✓ We can reformulate the problem as a “graph optimization problem”. Nodes are parameters to optimize, and edges are constraints.

# Bundle Adjustment

## ➤ Definition

- ✓ We jointly optimize camera poses of all the cameras and 3D points:

$$P^i, C_1, \dots, C_n = \underset{P^i, C_1, \dots, C_n}{\operatorname{argmin}} \sum_{k=1}^n \sum_{i=1}^N \rho \left( p_k^i - \pi(P^i, K_k, C_k) \right)$$

where  $\rho()$  is the Huber norm for robust estimation (introduced next week)

- ✓ We often use non-linear optimization, e.g., Gauss-Newton algorithm to minimize the error. Details will be introduced later.

# Bundle Adjustment

## ➤ Strategies for acceleration

- ✓ A small window size limits the number of parameters for the optimization and thus makes real time bundle adjustment possible.
- ✓ It is possible to reduce the computational complexity by just optimizing over the camera parameters and keeping the 3D landmarks fixed, e.g., motion-only BA.

A small window

Motion-only BA

# Bundle Adjustment

## ➤ Photometric Bundle Adjustment

We can extend the photometric error between 1-by-1 frames to 1-by-N frames.

$$\arg \min_{\lambda, \theta} \sum_{r=1}^F \sum_{\mathbf{x} \in \mathcal{I}_r} \sum_{f \in \text{obs}(\mathbf{x})} \|\mathcal{I}_r(\mathbf{x}) - \mathcal{I}_f(\mathcal{W}\{\mathbf{x}; \theta_f, \lambda_r(\mathbf{x})\})\|_2^2$$

"reference frame"

F-frames

# Non-linear Optimization

## ➤ Problem Formulation

✓ A teaser of curve fitting

Input: A set of observed discrete points (no outliers here)

Step 1: Select a suitable model/function with unknown parameters

Step 2: Estimate the parameters by the least-squares method: We define an objective function, i.e., the sum of squared distances.

# Non-linear Optimization

## ➤ Motivation of Gradient Descent Algorithm

To minimize the function, we can employ first-order optimality condition

$$\min_{\mathbf{x}} F(\mathbf{x}) = \frac{1}{2} \|f(\mathbf{x})\|_2^2 \quad \frac{dF}{d\mathbf{x}} = \mathbf{0}$$

If the derivative is simple, we can directly obtain the global minimum of objective function. However, what if the objective function is more complex?

1D function

$$\frac{d}{dw} g(w) = 0$$

2D function

$$\frac{\partial}{\partial w_1} g(\mathbf{v}) = 0$$

$$\frac{\partial}{\partial w_2} g(\mathbf{v}) = 0$$

$$\vdots$$

$$\frac{\partial}{\partial w_N} g(\mathbf{v}) = 0$$

# Non-linear Optimization

## ➤ Motivation of Gradient Descent Algorithm

Instead of directly obtaining the global minimum, we iteratively minimize the function.

$\mathbf{x}_k$  is a temporary value. It is known.

$\Delta\mathbf{x}_k$  is the adjustment of the above temporary value. It is unknown.

1. Give an initial value  $\mathbf{x}_0$ .
2. For  $k$ -th iteration, we find an incremental value of  $\Delta\mathbf{x}_k$ , such that the object function  $\|f(\mathbf{x}_k + \Delta\mathbf{x}_k)\|_2^2$  reaches a smaller value.
3. If  $\Delta\mathbf{x}_k$  is small enough, stop the algorithm.
4. Otherwise, let  $\mathbf{x}_{k+1} = \mathbf{x}_k + \Delta\mathbf{x}_k$  and return to step 2.

# Non-linear Optimization

## ➤ Steepest method

Now consider the  $k$ -th iteration. Suppose the current solution is at  $\mathbf{x}_k$  and we want to find the increment  $\Delta \mathbf{x}_k$ . For problem simplification, we use the first-order Taylor expansion to re-write the objective function:

$$F(\mathbf{x}_k + \Delta \mathbf{x}_k) \approx F(\mathbf{x}_k) + \mathbf{J}(\mathbf{x}_k)^T \Delta \mathbf{x}_k$$

Known      Known      Unknown

Gradient (Jacobi Matrix)

Along the minus gradient **direction**, we can ensure that the function decreases:

$$\Delta \mathbf{x}^* = -\mathbf{J}(\mathbf{x}_k)$$

We do not explicitly  
compute  $\Delta \mathbf{x}$

$\Delta \mathbf{x}$  is only a **direction**. We also manually select another **step length parameter (learning rate)**, say,  $\lambda$ . The smaller function value is  $F(\mathbf{x}_k) - \mathbf{J}(\mathbf{x}_k)^T \lambda$

# Non-linear Optimization

➤ Newton's method

$$F(\mathbf{x}_k + \Delta\mathbf{x}_k) \approx F(\mathbf{x}_k) + \mathbf{J}(\mathbf{x}_k)^T \Delta\mathbf{x}_k + \frac{1}{2} \Delta\mathbf{x}_k^T \mathbf{H}(\mathbf{x}_k) \Delta\mathbf{x}_k$$

We can also use the second-order Taylor expansion to re-write the objective function:

$$\Delta\mathbf{x}^* = \arg \min \left( F(\mathbf{x}) + \underbrace{\mathbf{J}(\mathbf{x})^T}_{\text{Known}} \Delta\mathbf{x} + \frac{1}{2} \Delta\mathbf{x}^T \underbrace{\mathbf{H}}_{\text{Unknown}} \Delta\mathbf{x} \right)$$

We leverage the first-order optimality condition, i.e., computing the derivative with respect to  $\Delta\mathbf{x}$  and setting the result to zero. We thus can obtain

$$\mathbf{J} + \mathbf{H}\Delta\mathbf{x} = 0 \Rightarrow \mathbf{H}\Delta\mathbf{x} = -\mathbf{J}$$

↑  
Hessian matrix

# Non-linear Optimization

## ➤ Gauss-Newton Method

### ✓ Motivation

**Steepest method** results in the zig-zag descending trajectory

**Newton's method** is time consuming due to the computation of Hessian matrix

$$\mathbf{H}_f = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1^2} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_1 \partial x_n} \\ \frac{\partial^2 f}{\partial x_2 \partial x_1} & \frac{\partial^2 f}{\partial x_2^2} & \cdots & \frac{\partial^2 f}{\partial x_2 \partial x_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f}{\partial x_n \partial x_1} & \frac{\partial^2 f}{\partial x_n \partial x_2} & \cdots & \frac{\partial^2 f}{\partial x_n^2} \end{bmatrix}$$

We need a more effective method: We will introduce a representative method “**Gauss-Newton algorithm**”.

# Non-linear Optimization

## ➤ Gauss-Newton Method

$$\min_{\mathbf{x}} F(\mathbf{x}) = \frac{1}{2} \|f(\mathbf{x})\|_2^2$$

Similar to the steepest method, we begin with first-order Taylor expansion

$$f(\mathbf{x} + \Delta\mathbf{x}) \approx f(\mathbf{x}) + \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x}$$

We aim to find the optimal  $\Delta\mathbf{x}$  to minimize this function

$$\Delta\mathbf{x}^* = \arg \min_{\Delta\mathbf{x}} \frac{1}{2} \|f(\mathbf{x}) + \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x}\|^2$$

Let us first expand this function:

$$\begin{aligned} \frac{1}{2} \|f(\mathbf{x}) + \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x}\|^2 &= \frac{1}{2} \left( f(\mathbf{x}) + \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x} \right)^T \left( f(\mathbf{x}) + \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x} \right) \\ &= \frac{1}{2} \left( \|f(\mathbf{x})\|_2^2 + 2f(\mathbf{x}) \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x} + \Delta\mathbf{x}^T \mathbf{J}(\mathbf{x}) \mathbf{J}(\mathbf{x})^T \Delta\mathbf{x} \right) \end{aligned}$$

# Non-linear Optimization

## ➤ Gauss-Newton Method

$$\frac{1}{2} \left( \|f(\mathbf{x})\|_2^2 + 2f(\mathbf{x})^T \mathbf{J}(\mathbf{x}) \Delta \mathbf{x} + \Delta \mathbf{x}^T \mathbf{J}(\mathbf{x}) \mathbf{J}(\mathbf{x})^T \Delta \mathbf{x} \right)$$

We compute the derivative of the above function with respect to  $\Delta \mathbf{x}$ , and then set the derivative to zero:

$$\mathbf{J}(\mathbf{x}) f(\mathbf{x}) + \mathbf{J}(\mathbf{x}) \mathbf{J}^T(\mathbf{x}) \Delta \mathbf{x} = 0$$

We transform the above into

$$\underbrace{\mathbf{J}(\mathbf{x}) \mathbf{J}^T(\mathbf{x})}_{\mathbf{H}(\mathbf{x})} \Delta \mathbf{x} = -\underbrace{\mathbf{J}(\mathbf{x}) f(\mathbf{x})}_{\mathbf{g}(\mathbf{x})}$$

We obtain a linear system to compute  $\Delta \mathbf{x}$

$$\mathbf{H} \Delta \mathbf{x} = \mathbf{g}$$

An approximation to Hessian matrix

# Non-linear Optimization

## ➤ Application to Bundle Adjustment (A Teaser)

- ✓ General objective function simplification by Gauss-Newton

$$e(x + \Delta x) \approx e(x) + \mathbf{J} \Delta x.$$

Jacobian matrix w.r.t. pose and point

Adjustment of camera pose and 3D point

- ✓ We have to compute derivative w.r.t. SO3/SE3. It involves addition and subtraction operation.
- ✓ Intuitively, R1 is in SO3 and R2 is in SO3, but we cannot guarantee that R1 + R2 is in SO3.
- ✓ To solve this problem, we first map Lie Group to Lie Algebra, and compute the derivative by Lie Algebra. More details will be introduced next week.

# Summary

- Error Metrics
- Bundle Adjustment
- Non-linear Optimization

Thank you for your listening!  
If you have any questions, please come to me :-)
